MATH H113: Honors Introduction to Abstract Algebra

2016-03-02

- Finish normal subgroups
- Isomorphism theorems

Note: We'll skip Section 3.4

Proof of Ex. 3.2.11 (p. 96):

Let $H \leq K \leq G$. Show that |G:H| = |G:K||K:H|.

Note: that we can't assume that G is finite. We also can't assume that H or K\$ is a normal subgroup of G. We'll assume that |G:H| is finite.

Map G/H to G/K by $uH \mapsto uK$.

This is well defined because $uH = vH \implies u^{-1}v \in H \implies u^{-1}v \in K \implies uK = vK$.

It's onto (surjective) because $\forall u \in G. uK = f(uH)$ (where f is the function we're defining).

Since $K/H \leq G/H$, $|K:H| < \infty$.

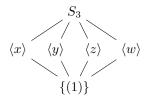

Let a_1H, \ldots, a_nH be the elements of K/H (without repetition). Then $K = a_1H \cup a_2H \cup \ldots a_nH$, and these cosets are disjoint (a_1, \ldots, a_n) are called a set of coset representatives of H in K). Then $\forall u \in G. uK = (ua_1)H \cup \ldots \cup (ua_n)H$, and again these cosets are disjoint.

So the fibers of $f: G/H \to G/K$ have n elements each $(vH \in f^{-1}(uK) \iff f(vH) = vK = uK \iff v \in uK \iff v \in ua_1H)$ for some $i \iff vH = ua_iH$ for some $i = 1, \ldots, n$.

 $\therefore |G:H| = n|G:K| = |G:K||K:H|.$

(f sorts the elements of G/H into piles of n elements each, and the number of piles is |G/K| = |G:K|

Back to Subgroups of S_3

We spent a lot of time showing that there were no subgroups between $\langle x \rangle, \langle y \rangle, \langle z \rangle, \langle w \rangle$ and S_3 . This is now immediate, because $|S_3:\langle x \rangle| = |S_3:\langle y \rangle| = |S_3:\langle z \rangle| = 3$ and $|S_3:\langle w \rangle| = 2$ are all prime. Which subgroups of S_3 are normal in S_3 ?

From earlier examples:

- $\{1\}$ and S_3 are normal (in S_3).
- $\langle x \rangle$ is not normal (in S_3).
- $\langle y \rangle, \langle z \rangle$ are also not normal (same reason as for $\langle x \rangle$).
- $\langle w \rangle$ is normal. This is because $|S_3:\langle w \rangle|=2$, and any subgroup of index 2 is normal.

If |G:H|=2 then the left cosets of H are H and the other one must be G-H. Likewise the right cosets are H and G - H.

 $\therefore gH = Hg$ because if $g \in H$ then gH = Hg = H otherwise gH = Hg because both = G - H.

Lagrange's theorem: if $H \leq G$ and |G| = n is finite, then |H| divides n. You don't necessarily have a subgroup of every order dividing n.

However you do have:

Theorem (Cauchy): If G is a finite group and p is a prime divisor of |G|, then G contains an element of order p (: it has a subgroup of order p: $\langle x \rangle$ where |x|=p).

Proof: On you homework.

Proposition: If H and K are finite subgroups of a group G, then $|HK| = \frac{|HK|}{|H \cap K|}$. **Proof**: See book, but it's the same idea as Ex. 3.2.11: map H to HK/K. The fibers have $|H \cap K|$ elements each.

Note: |HK| might not be a subgroup of G(|HK|) is defined as $\{hk: h \in H, k \in H\}$ K}, $HK/K = \{uK : u \in HK\}$).

Prop: Let H and K be subgroups of a group G. Then $|HK| \leq G \iff HK =$ KH.

Proof (sketch): If $HK \leq G$, then $\forall x \in HK$, $x^{-1} \in HK$, so $x^{-1} = hk$ with $h \in H, k \in K$.

 $\therefore x = k^{-1}h^{-1}$ lies in KH.

 $\therefore HK \subseteq KH$.

 $KH \subseteq HK$, let $x \in KH$; $x = kh \ k \in K, h \in H$.

Then $x^{-1} = h^{-1}k^{-1}$ lies in HK, so $x \in HK$ since $HK \leq G$.

 $\therefore KH \subseteq HK$. This proves " \Longrightarrow ".

" $\Leftarrow =$ ": Clearly $HK \neq \emptyset$,

Let $a, b \in HK$. Then $a = h_1k_2$ and $b = h_2k_2$ $h_1, h_2 \in H$; $k_1, k_2 \in K$.

Then $ab^{-1} = h_1k_1k_2^{-1}h_2^{-1}$ $k_1k_2^{-1}h_2^{-1} \in KH$, \therefore it's in HK, so it equals h_3k_3 $(h_3 \in H, k_3 \in K)$

 $\therefore ab^{-1} = h_1h_3k_3 \text{ lies in } HK.$

 $\therefore HK$ is a subgroup.

Corollary: If $H \leq N_G(K)$ then HK is a subgroup. In particular, if $K \triangleleft G$ then $HK \leq G$.

Proof: $HK = \bigcup_{h \in H} hK = \bigcup_{h \in H} Kh = KH$.

Isomorphism Theorems

Theorem (1st isomorphism theorem): Let $\phi: G \to H$ be a homomorphism. Then $\ker \phi$ is a normal subgroup of G, and $\operatorname{Im} \phi \cong G/\ker \phi$ (via $\phi(u) \leftarrow u(\ker \phi)$) **Proof**: This was done in Sect. 3.1

Corollary 1: $\phi: G \to H$ is injective $\iff \ker \phi = 1$.

Proof: If ker $\phi = 1$ then fibers of ϕ all are cosets of ker ϕ (or \emptyset), \therefore they have $|\ker \phi| = 1$ element each (or 0), so ϕ is injective.

If ker $\phi \neq 1$ then ker ϕ has two distinct elements, and they map to $1 \in H$.

Corollary: $|G : \ker \phi| = |\operatorname{Im} \phi|$

Proof: $|G : \ker \phi| = |G/(\ker \phi)| = |\operatorname{Im} \phi|$ (use isomorphism).

Anatomy of a homomorphism: let $\phi: G \to H$ be a homomorphism. $G \xrightarrow[\text{surjective}]{\pi} G/(\ker \phi) \xrightarrow[\text{injective}]{\pi} H$

 $\operatorname{Im} \phi \to H$ is the inclusion map $x \mapsto x$. It is a homomorphism.

Theorem (2nd isomorphism theorem, "diamond"): Let A and B be subgroups of G, and assume that $A \subseteq N_G(B)$ (for example, $B \subseteq G$). Then AB is a subgroup of $G, B \subseteq AB, A \cap B \subseteq A$, and $AB/B \cong A/(A \cap B)$ via $aB \leftarrow a(A \cap B)$.

Proof: $AB \leq G$ is proved already.

 $B \subseteq AB$ because $N_{AB}(B) \supseteq B \ (B \le AB)$

 $N_{AB}(B) \supseteq A$ by assumption $(N_{AB}(B) = N_G(B) \cap AB)$

 $\therefore N_{AB}(B) = AB$ because " \supseteq " is proved above, " \leq " is from the def.
